

MAGI-80 color-response palette studies

These plates compare the same 256-color sample of MAGI-80's logical 12-bit RGB gamut after each proposed photographic-film or historical-video response. They are design references for the palette system described in the main specification, not claims of exact manufacturer-approved film simulation.

Reading the grid

The full MAGI-80 color space contains 4,096 logical values (0xRGB, four bits per component). The generator builds a 24-bit output for every one of those values, then displays this shared 256-color subset:

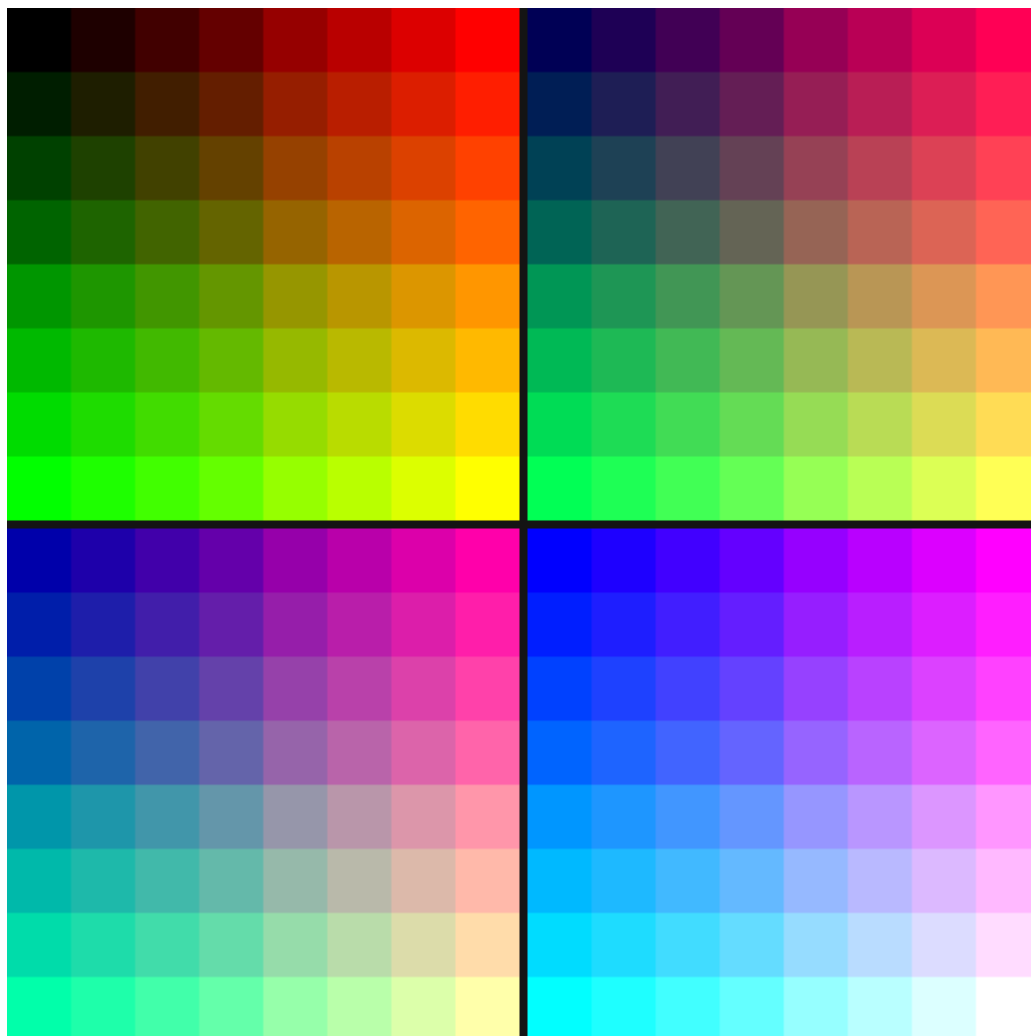

- red and green use levels 0, 2, 4, 6, 9, 11, 13, 15;
- blue uses levels 0, 5, 10, 15;
- the four 8 × 8 quadrants are the four blue levels, ordered top-left, top-right, bottom-left, bottom-right;
- within each quadrant, red increases from left to right and green from top to bottom.

This gives 8 × 8 × 4 = 256 samples distributed regularly through RGB12. Every plate preserves this exact ordering, so corresponding cells can be compared directly.

Amiga RGB12 — vanilla (1985)

The unfiltered reference expands each 4-bit component by nibble replication ($0xRGB \rightarrow 0xRRGGBB$). The 1985 date refers to the original Amiga RGB12 palette convention; an AGA machine can instead program each selected color with a full 24-bit value.

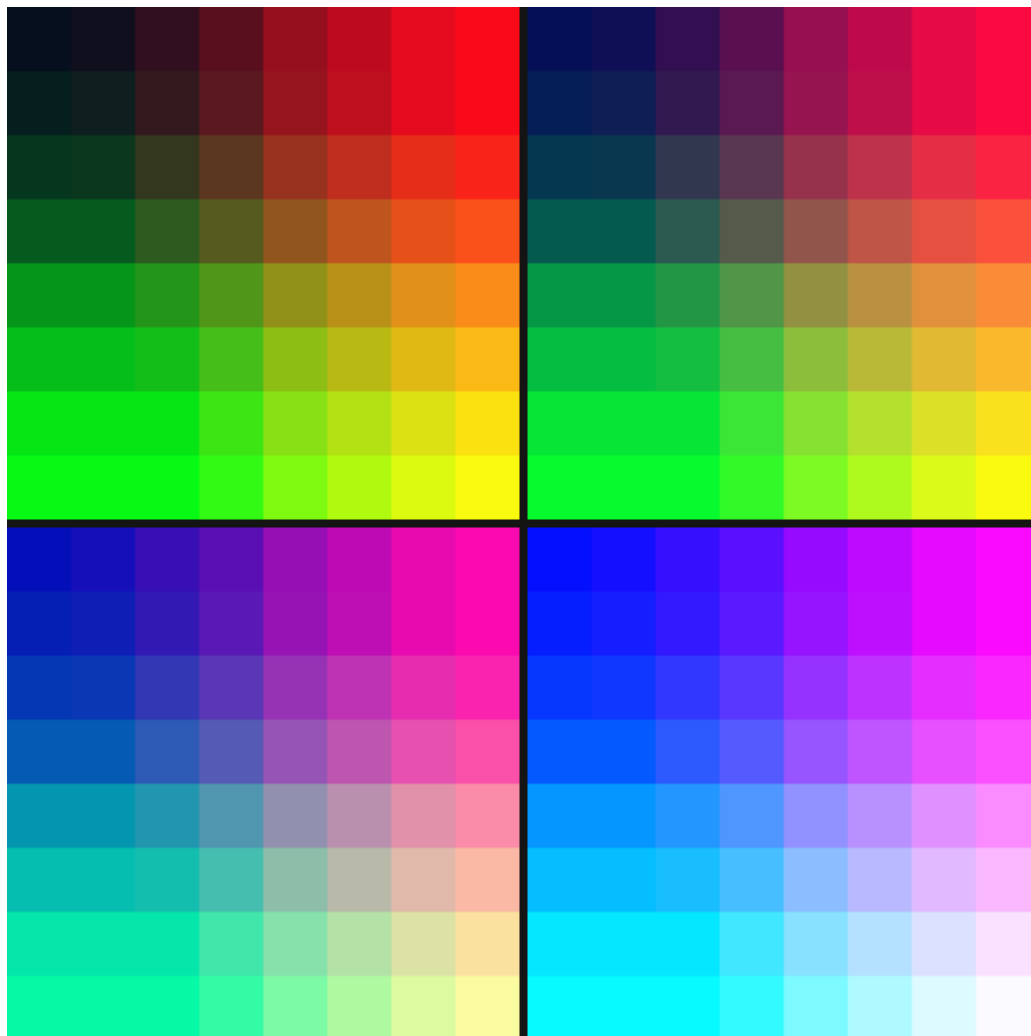

Kodak Professional PORTRA 400 (2010)

Soft toe and shoulder, restrained saturation, warm highlights, and a comparatively gentle blue response. The year identifies the unified PORTRA 400 formulation introduced in 2010, replacing the former NC and VC variants.

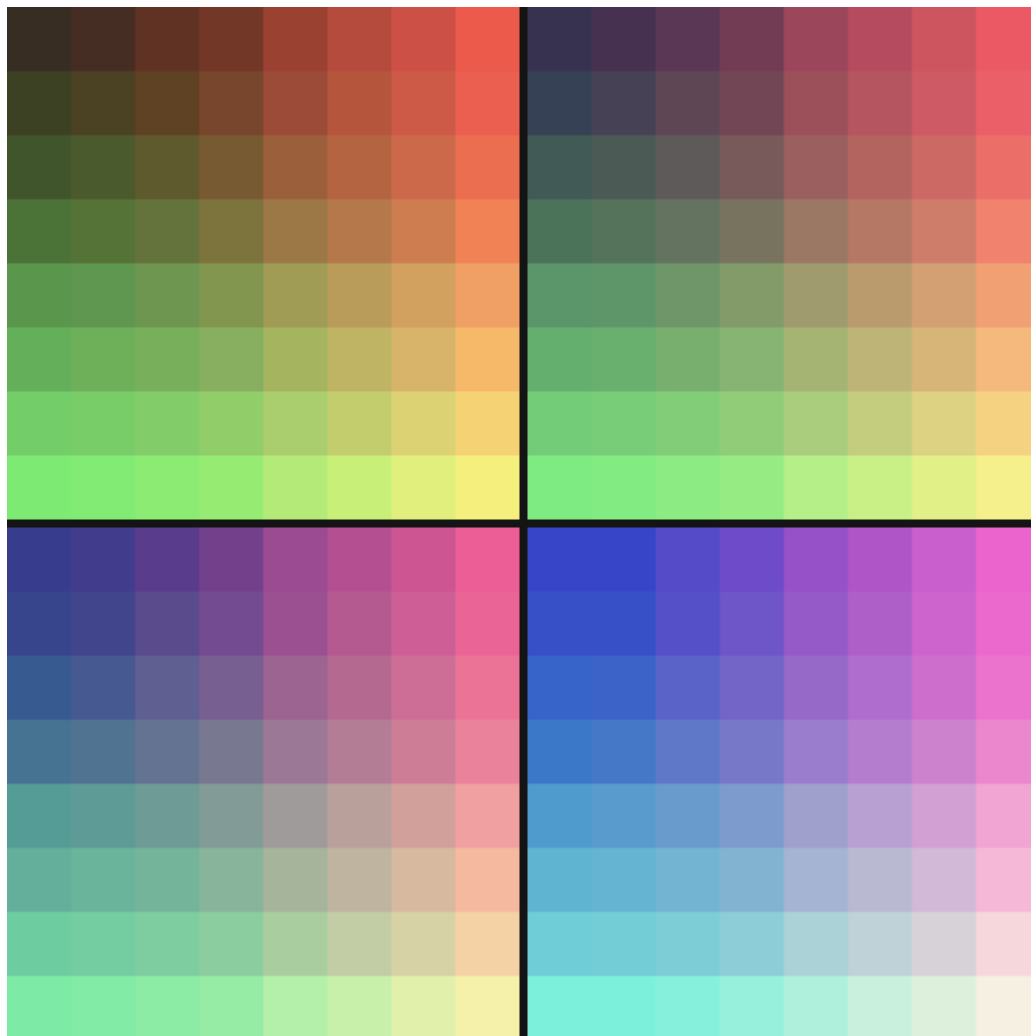

Kodak Professional EKTACHROME E100 (2018)

A reversal-film response with a firmer characteristic curve, clean highlights, and moderately reinforced blue/cyan and saturation. The year identifies the current E100 reintroduction, not the much older EKTACHROME family name.

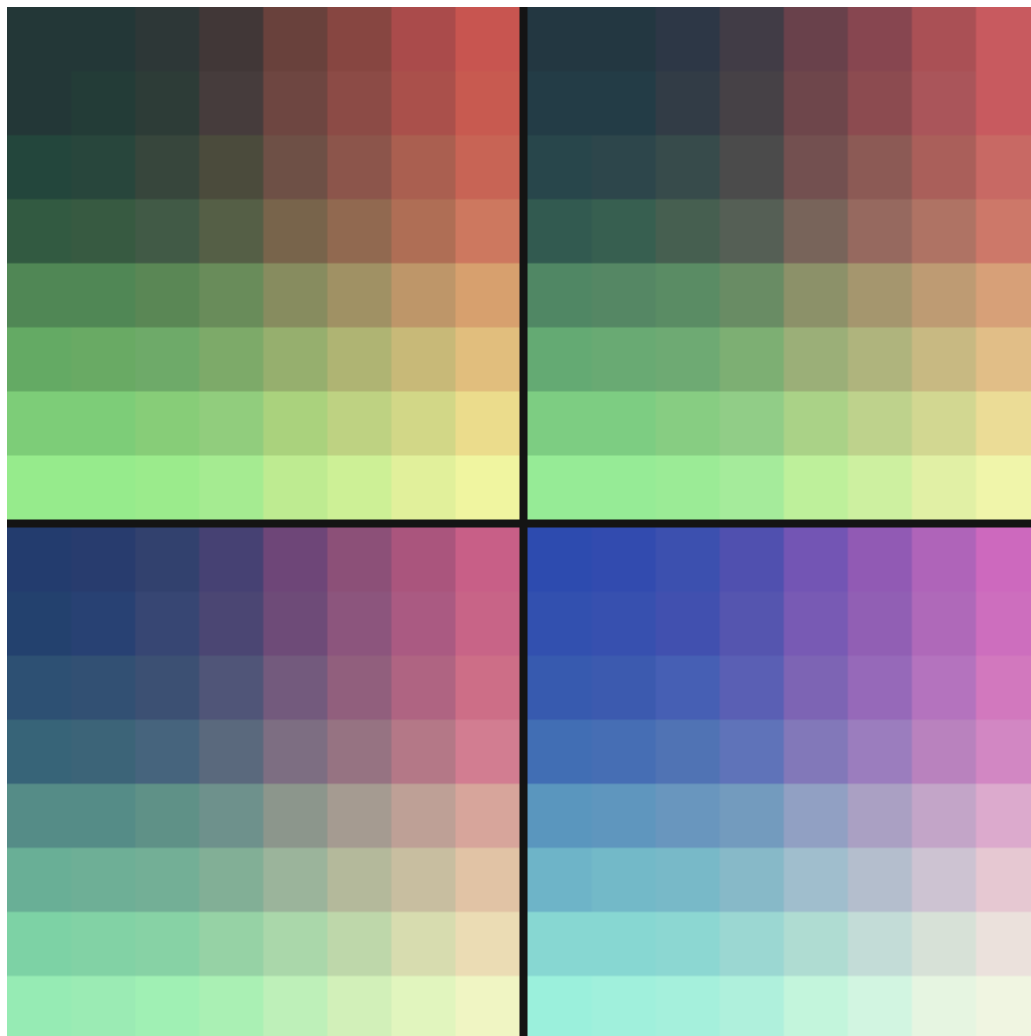

Polaroid Color 600 (1981)

Lifted blacks, compressed highlights, lower chroma, and a warm instant-print balance. The reference year is the introduction of Polaroid's ASA 600 integral-film system; current Color 600 chemistry is not assumed to be identical to the 1981 material.

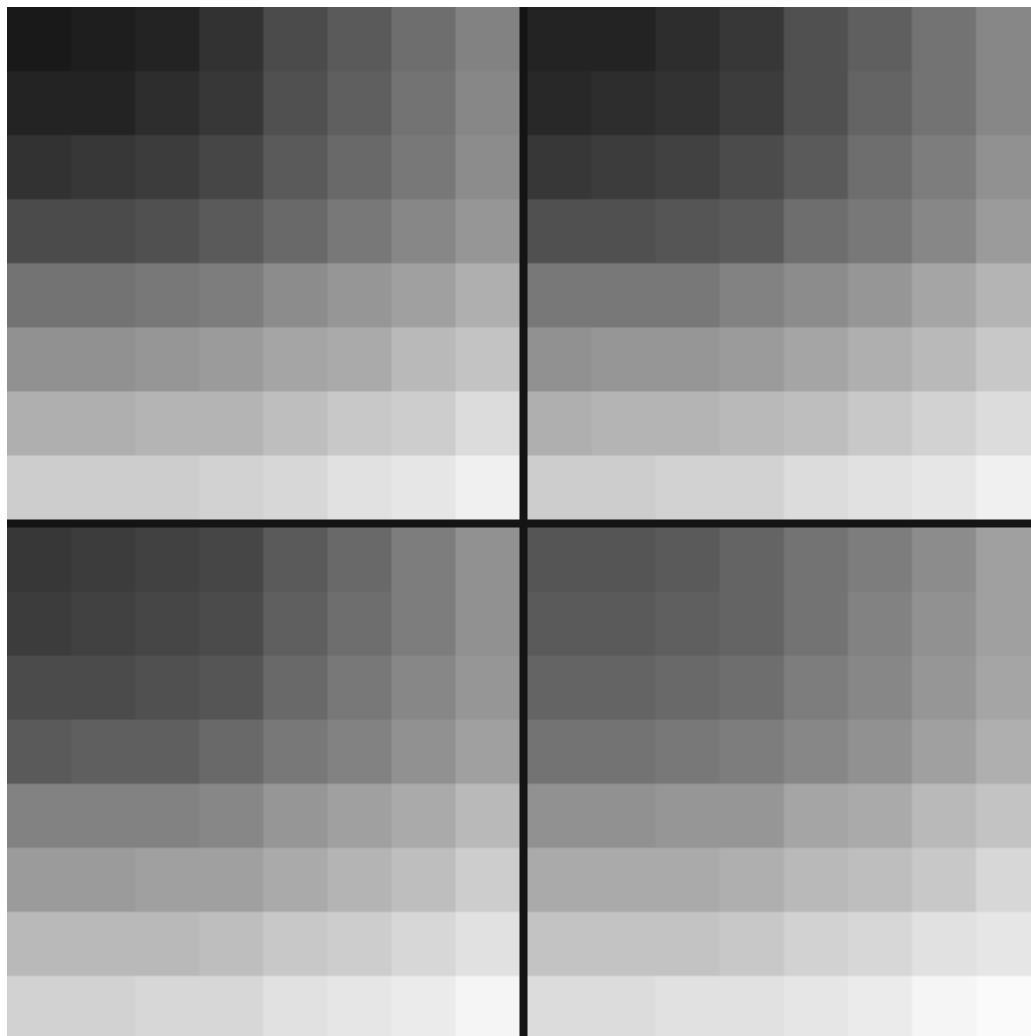

Lomography LomoChrome Metropolis (2019)

Muted chroma, strong contrast, cool green/cyan shadows, and warmer highlights, following the stock's stated "muted tones" direction. LomoChrome Metropolis was introduced in 2019.

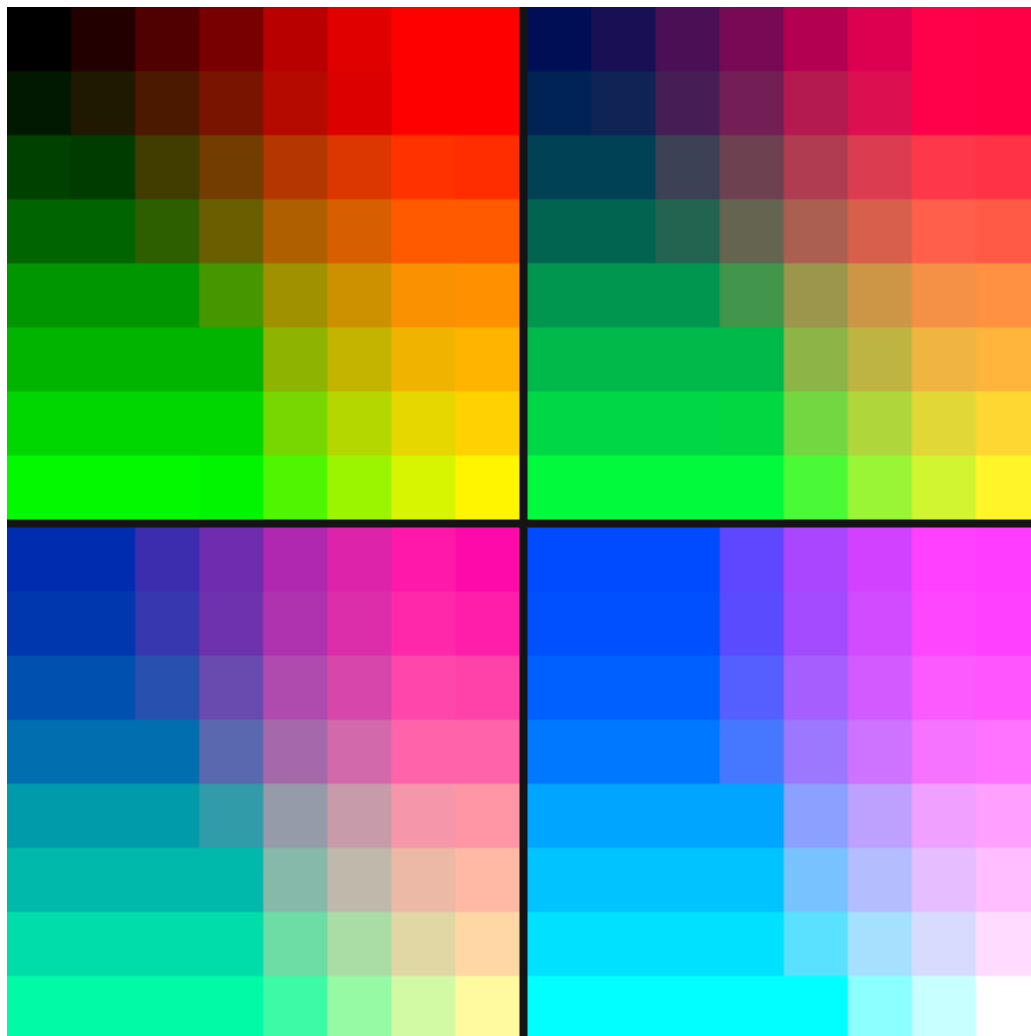

ILFORD HP5 PLUS (1989)

Neutral monochrome output derived from a panchromatic weighting, with a modest toe and shoulder. The RGB weights intentionally differ from ordinary display luma so the result can follow HP5 PLUS's broad spectral sensitivity more closely. HP5 PLUS was introduced in 1989; the earlier HP5 dates to 1976.

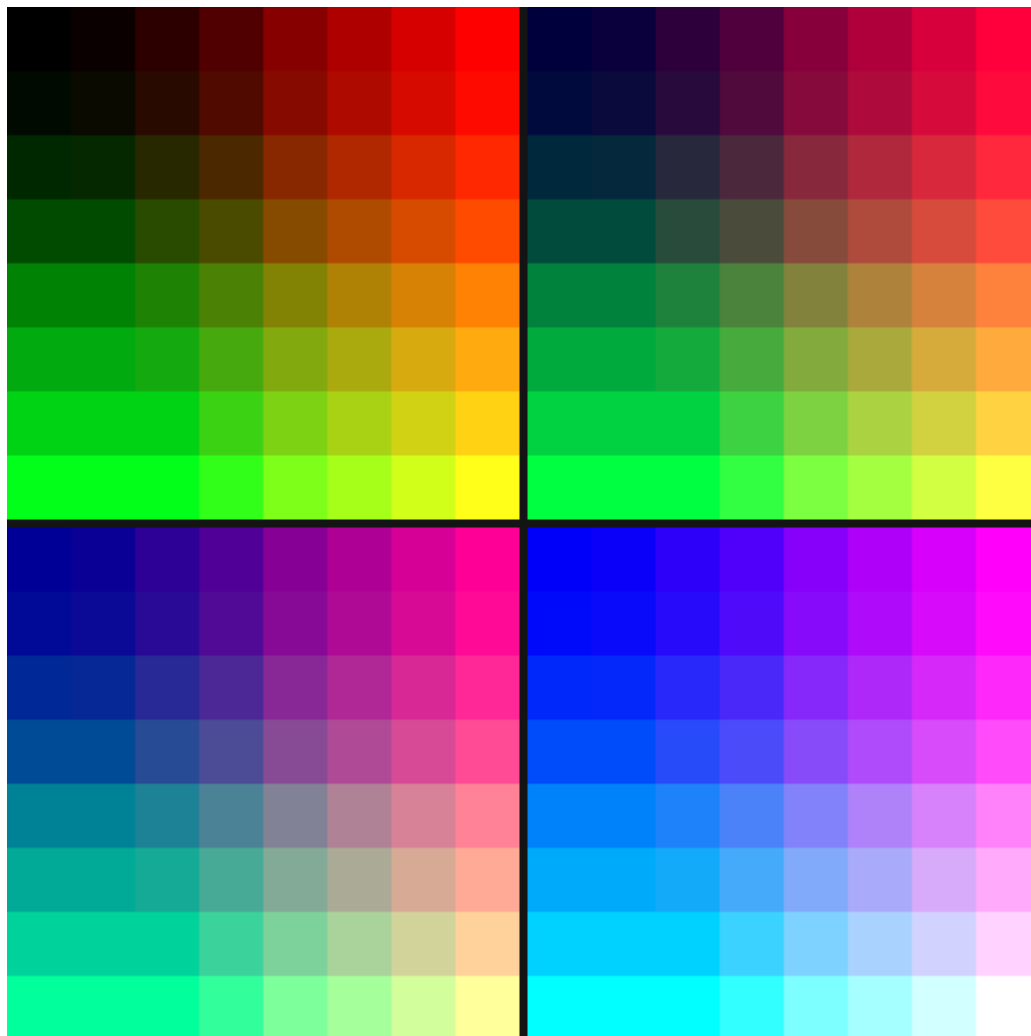

NTSC 1953 (1953)

The static colorimetric component uses the original NTSC 1953 primaries and Illuminant C reference white, adapted to the PNG's D65 sRGB display space. It does not add composite-video artifacts such as hue error, dot crawl, or bandwidth-dependent bleeding.

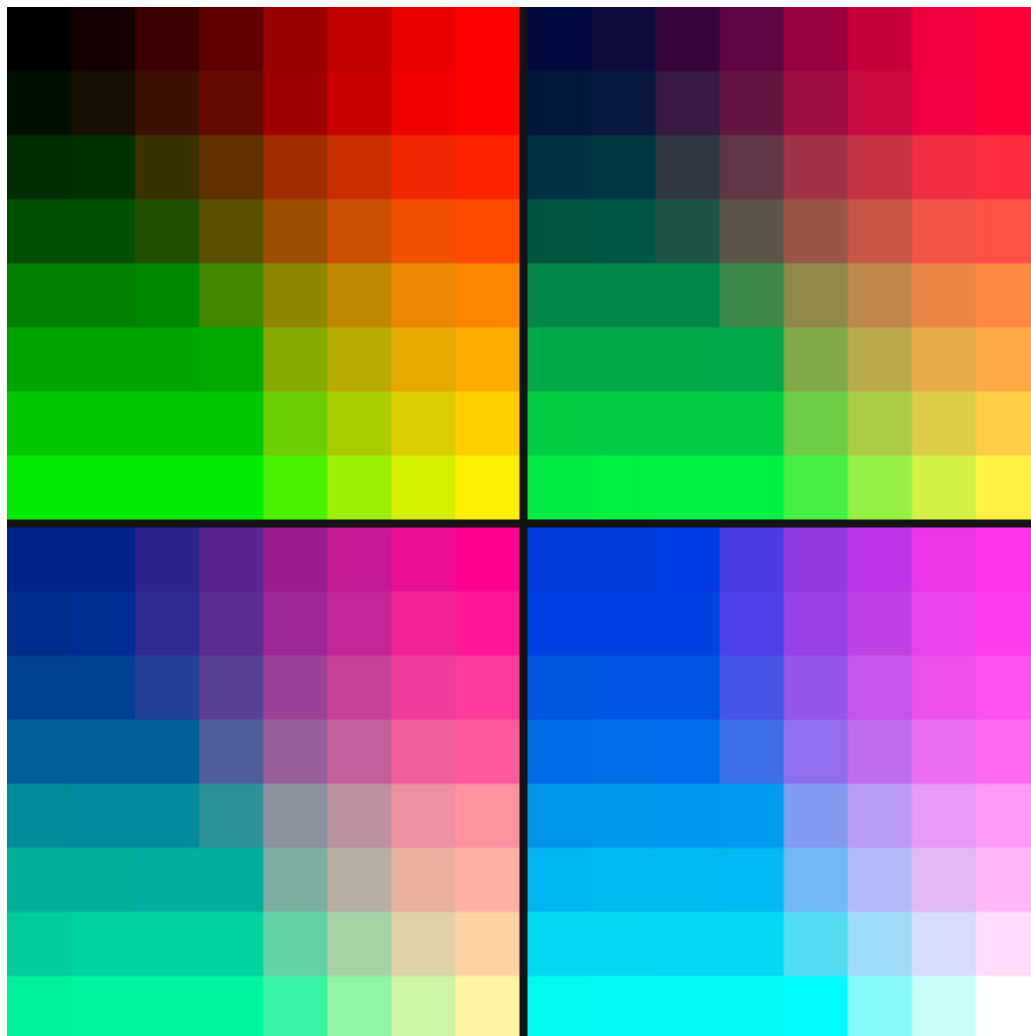

625-line PAL/SECAM (1967)

PAL and SECAM differ as transmission systems, but this shared palette response uses the 625-line primary chromaticities and D65 white documented by ITU-R BT.470. The 1967 date marks their regular public introduction in Europe. Line alternation, SECAM's sequential chroma, and other spatial or temporal behavior cannot be represented by a pointwise palette LUT.

Soviet OSKM / OCKM (1960)

OSKM—**Одновременная совместимая система с квадратурной модуляцией**, or “simultaneous compatible system with quadrature modulation”—was the experimental Soviet 625/50 color system broadcast in Moscow from 1960 before SECAM was adopted. The plate treats it as a period NTSC-derived, U/V-coded system and applies a conservative asymmetric chroma contraction. That contraction is explicitly a reconstruction assumption until primary receiver measurements or sufficiently detailed period specifications are available.

Reproduction and fidelity

Run the dependency-free generator from the repository root:

```
python3 documentation/color-response-palettes/generate_palettes.py
```

The generator evaluates all 4,096 RGB12 inputs for each profile, validates 8-bit output bounds, and writes sRGB-tagged, 516 × 516 RGB PNGs. Its matrices, tone curves, gamut clipping, panchromatic weighting, and historical-video colorimetry are visible in `generate_palettes.py`.

The present film transforms are reproducible visual baselines. A release-quality claim of physical fidelity requires digitized manufacturer spectral-sensitivity, characteristic, and dye-density curves where available, plus controlled color-target captures for stocks whose makers do not publish enough data. The target stock, processing chemistry, illuminant, print or scanner path, reference white, and fitting error must all be recorded. A static 4,096-entry palette LUT can reproduce color and tone mapping, but not grain, halation, local exposure effects, optical flare, chroma delay, scanlines, or noise.
